

"Turning effect of a force also called moments of a force"

definition: Product of forces and the perpendicular distance b/w the force and the pivot.

eg ①

$$\text{Moments} = 20 \times 4 = 80 \text{ Nm}$$

eg ②

Since force (when extended) passes through the pivot \therefore perpendicular distance = 0 hence

$$\text{Moments / Turning effect} = 0 \text{ Nm}$$

eg ③

$$d = 10 \sin 60^\circ$$

$$\text{Moments} = F \times d = (10 \sin 60^\circ) \times (8) = 69 \text{ Nm}$$

method ②

$$\sin 60^\circ = \frac{d}{8}$$

$$d = 8 \sin 60^\circ$$

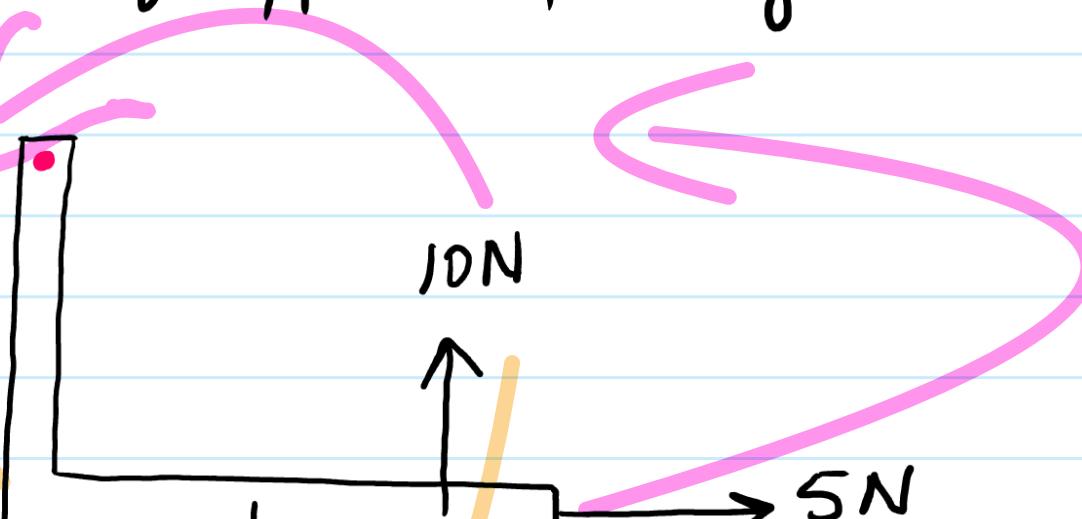

$$\text{Moments} = F \times d = 10 \times (8 \sin 60^\circ) = 69 \text{ Nm}$$

- What are the conditions for Equilibrium
- ① Turning effect = 0
(i.e. C.W.M = A.C.W)
- ② Resultant force = 0
(upward force = downward force
(Left force = right force)).

Graph of F vs d?

$$\text{Moment} = F \times d \quad F \propto \frac{1}{d} \text{ (inversely prop.)}$$

Q How to form equation using Principle of moments.

Q, How to find the Resultant moments?
Concept of resultant moments will only arise if one turning effect (either C.W or A.C.W) is greater/less than the other turning effect for eg.

Cal. the Resultant Turning effect?

$$\text{A.C.W} = 5 \times 5 = 25 \text{ Nm} \quad \text{C.W} = 20 \times 2$$

$$\text{A.C.W} = 10 \times 5 = \frac{50 \text{ Nm}}{75 \text{ Nm}} \quad = \frac{40 \text{ Nm}}{40 \text{ Nm}}$$

Resultant moments

Resultant Torque = 35 Nm (ACW).
